The background image is an underwater scene. In the foreground, a large, dark pipeline runs diagonally across the frame. The seabed is sandy with sparse green vegetation and some rocks. In the background, there is a large, cylindrical structure, possibly a wellhead or part of an offshore platform, with a complex lattice of pipes and supports. A hammerhead shark is visible in the water, swimming towards the right. The overall lighting is dim and greenish, typical of an underwater environment.

Predictive Axial Walking An Evidence Based Approach

Derek Scales – Atteris Pty Ltd

22nd February 2017

- Axial Walking
- Evidence Based Operations
 - Integrity Management
 - Learning
 - Operations Analogy
- Axial Walking Operations Tool
- Evidence Based Methodologies and Repair Strategies
 - Planning
 - Repair selection

Pipeline Expansion on Seabed

$$T = \text{Amb}$$

$$P = \text{Amb}$$

$$\mu = 0.7$$

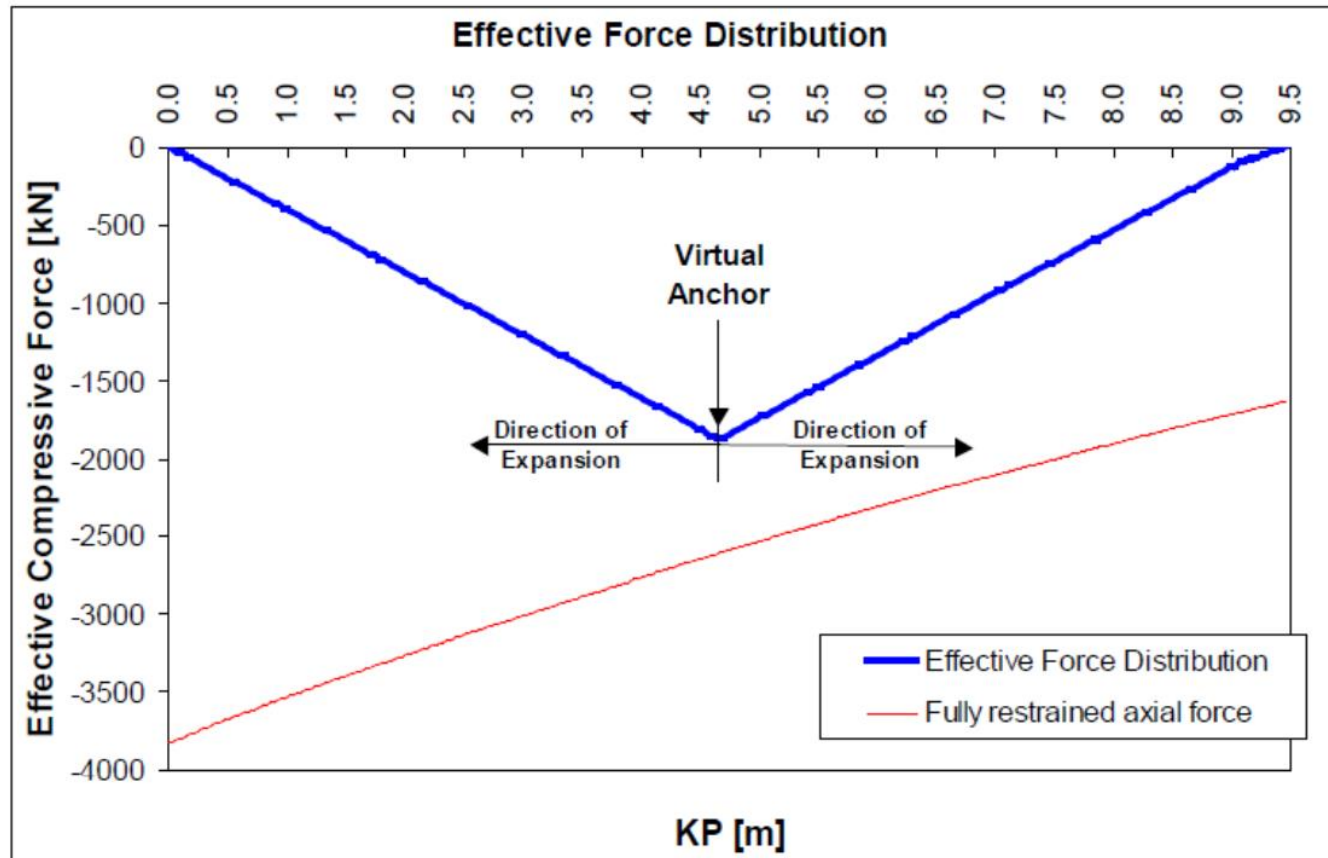

Pipeline Expansion on Seabed

$$T = HT$$
$$P = HP$$
$$\mu = 0.7$$

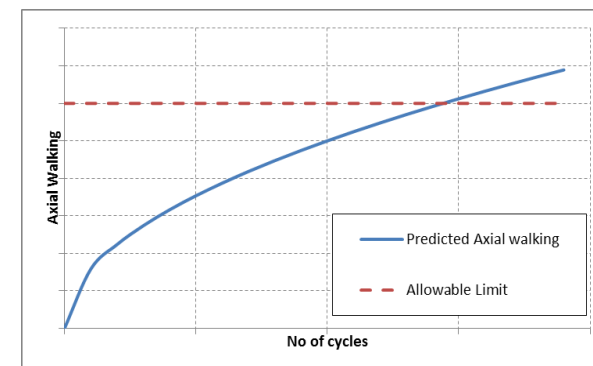

Axial Walking

- Short Pipeline – Does not reach the fully restrained effective axial force

Axial Walking

- *Short* pipelines expand and contract about their virtual anchor point
- How do we get axial walking?
- Asymmetry in some way that moves the virtual anchor point from the middle
 - Seabed slope (walk down the hill)
 - Steel catenary riser (walk towards the end being pulled)
 - Thermal transients (walk towards the 'cold' end)
 - Ratcheting of lateral buckles for long pipelines
 - Or combinations of the above...
- Need to produce a system that can either prevent axial walking or allow for the axial walking over the asset life
 - Anchors
 - Large spools or sliding termination assemblies

Axial Walking Predictions – Design Phase

- Requires Finite Element Analysis in the Design Phase
- Complicated models
 - Operational cycles
 - Material properties
 - Pipe / soil interaction
 - Seabed undulations / slopes
 - Etc.
- Time consuming process to develop a suitable prediction of axial walking.

Operations **is** our 1:1 scale model

As with all “*testing*” we should utilise the data produced

Validates the design behaviour and that our operating and integrity limits are acceptable

The art of proving consistent behaviour

How do we prove consistent **behaviour**?

By collecting **evidence**.

So what **evidence** is important?

All **evidence** is important.

“Evidence”

Provides insight to actual behaviour and substantiates predictive behaviour

What is difficult about evidence?

The assemblage of evidence

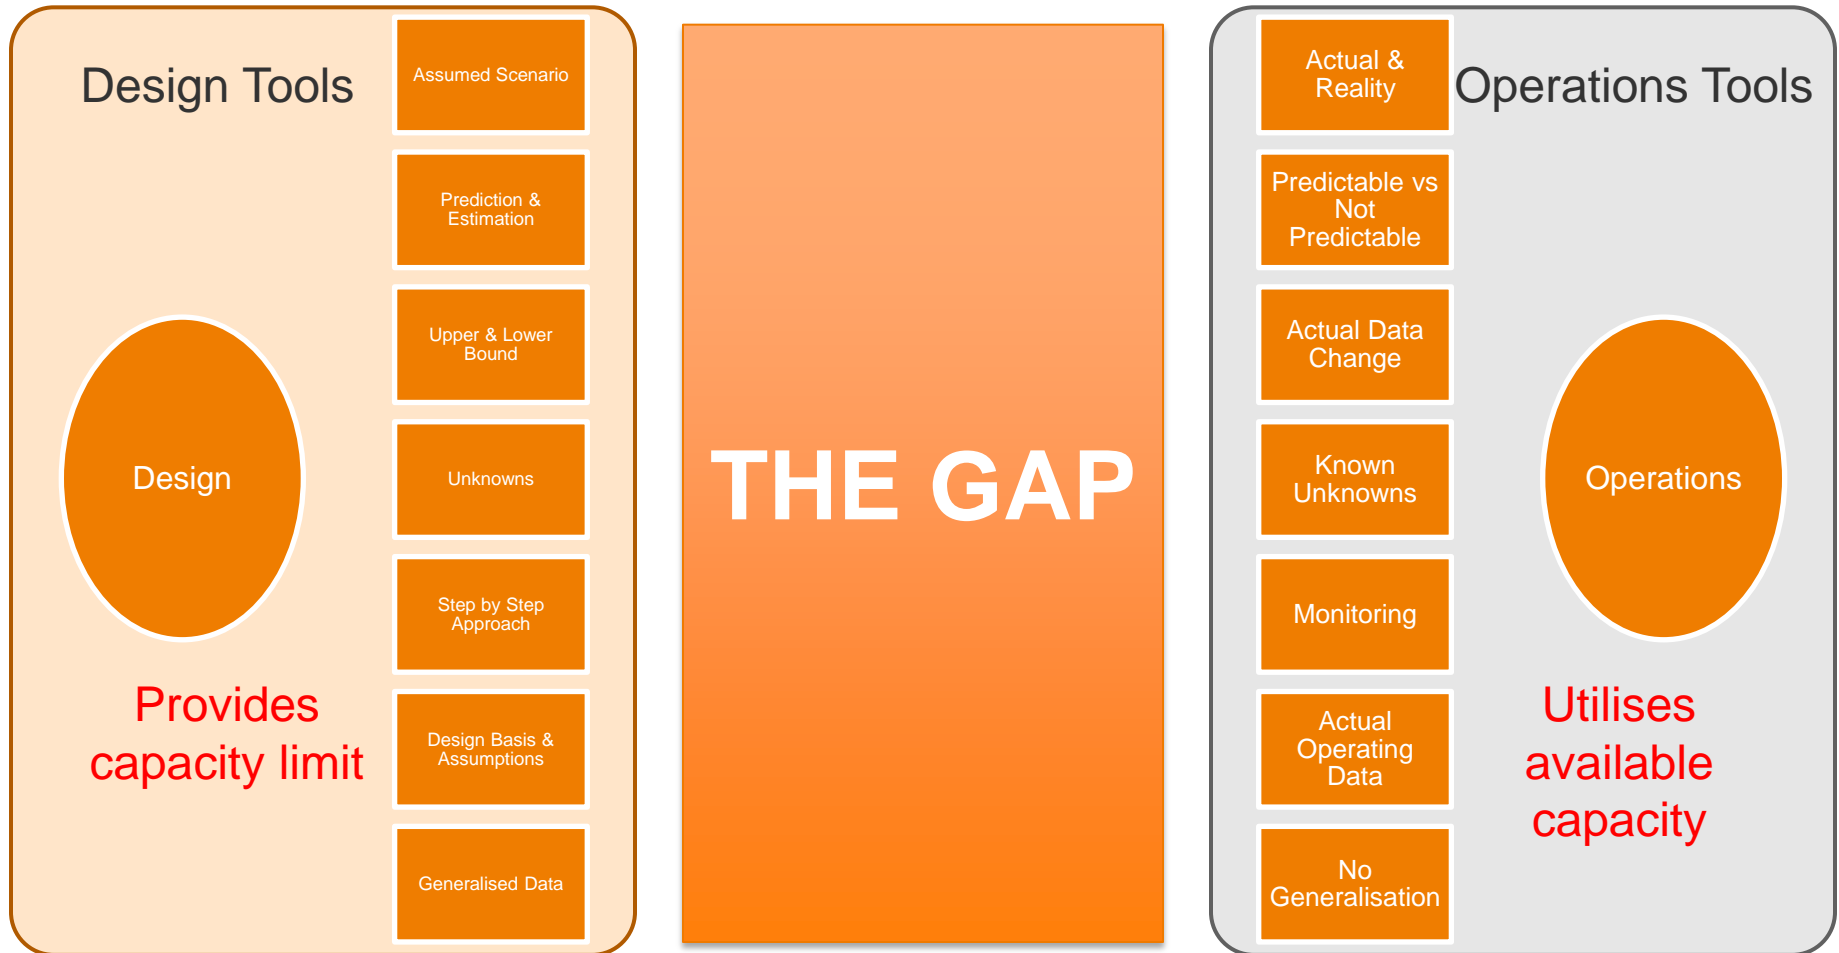

Knowing how discrete pieces of evidence interact to yield the overall result

Knowing what you are looking at and how it interacts can be the difference between success or not

Understanding the system behaviour in real life conditions allows appropriate intervention to be undertaken

Fit For Purpose Tools

How best to utilise the Evidence?

- For axial walking one option is to feed the data collected back in to the design tool.
- Complicated models
 - Operational cycles
 - Material properties
 - Pipe / soil interaction
 - Seabed undulations / slopes
 - Etc.
- Limited evidence of actual behaviour
- Time consuming and labour intensive process to match behaviour of the model with the observed behaviour of the actual pipeline.

Axial Walking Operations Tool

- Alternative approach developed to use the available evidence of past behaviour to directly predict future behaviour.

Repair Strategies

- Design is the base case plan
- Things do not always go to plan
- Intervention required
 - Repair
 - Replace
 - Mitigate.

Repair Strategies

Reliable data and a learned predictive behaviour can help optimise intervention work

Suitable intervention methodology

Scheduling

Is intervention required?

Situation specific information

Uses company knowledge

- Predictive tool
- Utilises current knowledge to drive the predictive tool
- The tool learns and can improve the axial walking prediction
- Provides assurance in the design
- Aid in determining if intervention work is required

- The predictive nature of the tool allows potential issues to be spotted early allowing increased planning time for intervention strategies
- Provide input to the design of the intervention strategy.

A 3D rendered scene with a monochromatic olive-green color palette. In the foreground, a large, dark pipe runs diagonally across the frame. The ground is sandy and sparsely covered with small, tufted plants. In the background, a tall, cylindrical tower with a lattice structure stands on the left. To the right, a shark swims in the water. The overall atmosphere is desolate and industrial.

THANK YOU
